? The open-ended question is to know which relations are formed in this concept. My best understanding is that they are formed by the conjunction of membership and equivalence. I did try to derive some properties but I got some twisted set theory. Is it a valid set theory? Also, what is the best source to get more information on the concept? A: Your understanding is correct. A reflexive relation is a relation such that there exists a tuple $\langle x,x\rangle$ in the relation and $\langle x,y\rangle\in R$ iff $x=y$. This is called self-referential condition. For example $S=\{(x,y)\mid y\in x\}$ is reflexive and anti-reflexive. A reflexive relation is a relation that contains $\langle x, x\rangle$ for all x. A transitive relation is a relation that contains $\langle x, y\rangle$ and $\langle y, z\rangle$ whenever $\langle x, y\rangle$ and $\langle y, z\rangle$ are in the relation. A non-symmetric relation is a relation that contains $\langle x, y\rangle$ but does not contain $\langle y, x\rangle$. Σ-definable relations are relations that can be defined by a formula in the signature Σ of relations. Σ-formula (or just Σ) is a first-order formula that uses only variables in Σ as well as the relation symbols. Therefore, a Σ-formula $\varphi(x_1,\ldots,x_n)$ with n free variables is a relation between the free variables $x_1,\ldots,x_n$ such that for every structure $\mathcal{M}$ with domain M and a Σ-structure $\mathcal{N}$ with the same domain M, $\mathcal{N}\models\varphi(a_1,\ldots,a_n)$ iff $\mathcal{M}\models\varphi(a_1,\ldots,a_n)$ 82157476af
